

Mind the Gap: Does Discontinuity in Health Insurance Status Cause Increased Usage of Emergency Department and Physician Office Visits?

Maryaline Catillon and Emma Sandoe

Massachusetts, United States

Abstract

Background: The health insurance market will undergo significant changes as the Affordable Care Act extends health coverage to millions of Americans who were previously uninsured. Yet, little is known how changes to insurance coverage affect usage of medical services.

Objectives: Investigate the statistical associations between changes in insurance status (becoming insured or uninsured) in both emergency department (ED) use and physician office visits and compare differences in the impact of the insurance status change on ED compared to physician office visits.

Sample: This study utilizes survey data from 262 775 respondents to the the National Health Interview Survey (NHIS) from 2006 to 2009.

Method: Insurance status was categorized into four groups: continuously insured, newly insured, newly uninsured and continuously uninsured. This status was compared to ED and physician office visits rates.

Results: Newly insured patients use more ED visits than the other groups (0.53 visits a year vs 0.52 for newly uninsured, 0.39 for continuously insured and 0.34 for continuously uninsured). Continuously insured people use more physician visits than the other groups (4.5 visits per year vs 4.4 for newly insured, 3.8 for newly uninsured and 2.6 for continuously uninsured). Continuously uninsured individuals do not drive ED use and seek less care than people with other insurance statuses, both in the ED and physician offices (2.6 visits per year vs 3.9 for newly uninsured, 4.4 for newly insured and 4.5 for continuously insured). Regardless of insurance status, people seek medical care in the physicians office more than the ED. A gain in insurance status is associated with an increase in seeking medical care in both EDs and physician offices.

Keywords: Health Insurance, Emergency Department, Physician Use

1 **1. Introduction**

2 Although many believe that the uninsured drive emergency department (ED)
3 usage in the United States, studies have shown that in fact, the uninsured popula-
4 tion forgoes care and whereas the newly eligible population drives care to the ED.
5 (Weber:2008, Cheung:2011) Little is known about how ED usage compares with
6 other physician office visits for the uninsured population, in comparison to the newly
7 insured and those that have continuously had coverage.

8 The 2010 passage of the Patient Protection Affordable Care Act (P.L. 111-148)
9 and the changing economic climate means that millions of Americans are seeing their
10 health insurance status change. Economists have suggested that increased insurance
11 causes a moral hazard for individuals to seek care when that care had previously
12 been avoided due to lack of insurance. (Pauly: 1968)

13 Increased unemployment due to the 2008 recession and cuts in public insurance
14 programs increased the number of uninsured individuals. From 2006-2009 these
15 events caused people to cycle between being covered by insurance and being unin-
16 sured. Some studies have shown that uninsured people are most likely to seek care
17 in the ED over physician offices because of limited access to seeking care in other
18 care settings. (Cheung:2008, Ludwick:2009) A recent randomized controlled trial in
19 Oregon showed that newly insured Medicaid beneficiaries were more likely to use the
20 ED when first gaining coverage.

21 A previous study (Ginde: 2012) examined the relationship between Insurance
22 status change and ED usage utilizing the National Health Interview Study (NHIS)
23 from 2004 to 2009. The authors concluded that recent changes in health insurance
24 status for newly insured adults and for newly uninsured adults was associated with
25 greater ED use. The study described the proportion of people in each category using
26 the ED but did not show an association.

27 Our study proposes to use another statistical approach to further examine these
28 findings and investigate the association between health care utilization (including
29 both emergency department use and physician visits) and change in insurance cov-
30 erage status.

31 **2. Methods**

32 The National Center for Health Statistics within the Centers for Disease Con-
33 trol and Prevention (CDC) annually conducts the National Health Interview Survey

34 (NHIS). This is a cross sectional interview survey of families within the US popula-
35 tion. We used publicly available NHIS data from 2006 to 2009. For more on NHIS
36 methodology see: [http : //www.cdc.gov/nchs/nhis/questdatarelated1997forward.htm](http://www.cdc.gov/nchs/nhis/questdatarelated1997forward.htm)

37 From variables in the NHIS survey, we created four categories of individual cover-
38 age: (1) newly insured: if the survey respondent reported a lack of health insurance
39 at some point within the last 12 months, but were currently insured; (2) continu-
40 ously insured: if the survey respondent reported no lack of health insurance at some
41 point within the last 12 months, and were currently insured; (3) newly uninsured: if
42 the survey respondent reported a lack of health insurance at some point within the
43 last 12 months, but were currently uninsured; (4) continuously uninsured, if they
44 reported never having health insurance in the past 12 months and were currently
45 uninsured. The relationship between these groups of individuals are shown in a
46 descriptive analysis of these samples in Table 1.

47 Individuals with different health insurance types were categorized as having pri-
48 vate insurance (as well as those with other types of insurance including Medicare),
49 Medicaid (as well as those with Medicare and Medicaid), or Medicare only, other (if
50 reporting another type of insurance including military coverage), and uninsured.

51 The relationship between insurance status and usage rates in ED and physician
52 office visits was investigated using multivariable Poisson regression with factor anal-
53 ysis. Two-tailed $p < 0.05$ was considered statistically significant. Statistical analysis
54 utilized R.

55 3. Results

Figure 1: ED usage by insurance status.

56 People who are newly insured visit the ED most often followed by the newly
57 uninsured (0.54 visits per a year compared to 0.52). People continuously without
58 insurance visit the ED the least often (0.34 visits per a year). See Figure 1.

Figure 2: Physician office usage by insurance status.

59 Additional findings include continuously uninsured people are least likely to use
60 physician offices (2.3 visits per year vs 3.4 for the newly uninsured, 3.8 for the newly
61 insured and 4.1 for the continuously insured). The continuously insured are the
62 group that seeks the most care in the physician office. Newly insured seek more care
63 in the physician office than newly uninsured. See Figure 2.

Figure 3: Total care by insurance status.

64 Combined with ED usage and physician office usage, we found that people who are
 65 continuously insured seek the most care (4.5 visits per year) followed closely behind
 66 by people who are newly insured (4.4 visits per year). Newly uninsured seek more
 67 care than continuously uninsured (3.9 visits per year and 2.6 for the continuously
 68 uninsured). See Figure 3.

69 4. Discussion

70 People primarily use physician offices for medical services, regardless of insurance
 71 status and people with insurance status changes use the ED more than those with-
 72 out insurance status changes. The continuously insured use the most total medical
 73 services. This suggests that efforts to increase continuity in health insurance status
 74 may reduce ED use, if accompanied by increased access to physician office visits.

75 One weakness in using this data set is that it does not provide information re-
 76 garding when over the last 12 months people received their care. The individual's
 77 care may have triggered the insurance status change. For example, an uninsured
 78 person may seek care in any setting and the provider may find that they are eligible
 79 for Medicaid and enroll them, now categorizing them as newly insured.

80 Several types of research might be warranted given these findings. First, behav-
 81 iorally oriented investigation might seek to uncover the mechanism of the findings.
 82 Second, these findings need replication both under the Affordable Care Act and in

83 new delivery system models of care delivery (minute clinics, Accountable Care Or-
84 ganization models, etc.). It would be useful to explore whether ED and physician
85 office use varies geographically in order to target increased access to physician office
86 services to reduce unnecessary use of the ED.

87 **5. Conclusion**

88 Uninsured adults are often cited for high ED usage, but this analysis finds that
89 uninsured adults have ED use consistent with insured individuals. Continuously
90 uninsured individuals use the ED less often than continuously insured or newly
91 insured or uninsured. People with disruptions in insurance use (becoming newly
92 insured or uninsured) have the highest ED usage, regardless of insurance type or
93 health status. Continuously insured people use the physician office the most. These
94 data suggest that policy directed towards insurance stability and improved physician
95 office access may reduce unnecessary ED usage which may lower costs.
